

24-HOUR URINE, ALKALINIZED, FROZEN

DEAR PATIENT,

Your doctor often orders a laboratory test that requires collecting urine over a 24-hour period.

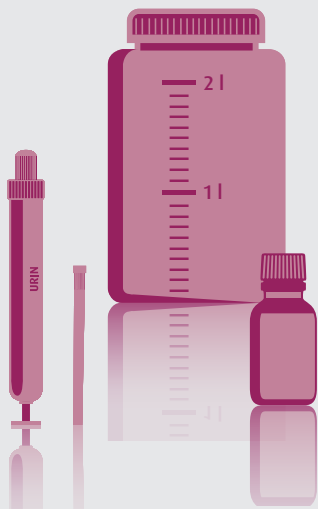

A sample of the collected urine will then be sent to the laboratory for testing.

It is important that all urine is collected completely over the full 24-hour period. It is also essential to accurately record the total 24-hour Urine Volume and the Collection period. The accuracy of the laboratory test depends on this information!

This guide explains how to collect the urine, label the samples, and store them correctly.

From the laboratory you will need:

- 24-hour urine collection container
- Urine tube for sample collection
- An alkali agent, such as Sodium Bicarbonate
- 1 Cool Transport Container
- 2 Urine transport containers

HOW DO YOU COLLECT 24-HOUR URINE?

What should you pay attention to?

- Place the cool transport container in the freezer compartment of a refrigerator before use.
- During the urine collection period, you should drink approximately 1.5 to 2 liters of fluid throughout the day.
- If you are testing uric acid, do not start a „healthy“ low-purine diet just for the test. Also avoid unusually high intake of purines (meat, shellfish, overeating), as this may temporarily increase uric acid excretion in urine. Avoid alcohol, especially excessive beer consumption.
- Please discuss with your doctor which medications you may take before and during the collection period.

How to collect urine?

- Urine is collected over a 24-hour period, for example:
 - Day 1: start at 08:00
 - Day 2: end at 08:00
- Collect the urine in a clean container (a special container is recommended, protected from light and marked with volume graduations).
- The collection period begins in the morning after waking up. Empty your bladder completely into the toilet. This urine is not collected, but note the time (e.g., 08:00); this marks the start of the collection period.
- For urine alkalinization, sodium bicarbonate (NaHCO_3) is used. Place 5–10 g of sodium bicarbonate into the 24-hour urine collection container before starting urine collection.
- Collect all urine passed over the next 24 hours in the 24-hour urine collection container, including the first morning urine on the second day. This marks the end of the collection period. Please also record this time (e.g., 08:00).
- During the collection period, store the urine in a cool place or in a refrigerator (2–8°C).

WHAT HAPPENS AFTER THE COLLECTION?

1. Reading the urine volume

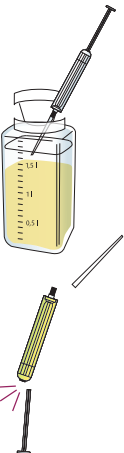

The urine collection container has graduated markings that allow you to read the urine volume. **Record the total 24-hour urine volume accurately!**

2. Mixing the collected urine

Gently swirl the urine collection container to ensure that the urine is well mixed. If you have filled more than one urine collection container, first pour the contents of all containers into a clean bucket.

3. Sample collection

Collect the urine sample using a special sampling tube (e.g., Urine Monovette, 10 mL). Remove the cap from the urine tube and attach the tip. Insert the tip into the urine collection container and fill 2 urine transport containers completely.

4. Labeling the sample

Label the tubes with your first and last name, and store them in the freezer compartment of a refrigerator until delivery to the Laboratory. Before bringing the samples to the laboratory, place the 2 frozen containers in the pre-frozen cool transport container

How should you proceed?

- All urine must be collected without exception — even during bowel movements.
- Store the urine collection container in a cool place whenever possible.
- If any urine sample is missed during the collection period, the collection must be restarted on another day.
